INLAjoint

Denis Rustand

2022-04-10

In this vignette we show how to fit various models with the joint() function of the INLAjoint package.

Dataset for illustrations

We use the data of the famous randomized clinical trial of Primary Biliary Cholangitis (PBC) patients where 312 PBC patients were followed at the Mayo Clinic between 1974 and 1988 and received either a placebo or D-penicillamine. These data are publicly available in several software including the R package JM. During the follow-up, 140 patients died and 29 patients received a liver transplantation which we consider here as a competing event of death. In addition, repeated measures of various longitudinal markers potentially associated with the disease progression were collected.

This vignette illustrates how to fit various joint model including multiple longitudinal markers and competing risks of events. The final model illustrated is a joint model for two competing risks of events and 5 longitudinal markers with different distributions as proposed in the application section of the following paper: https://arxiv.org/abs/2203.06256

Model 1: single longitudinal marker

This first model shows how to call the *joint()* function for a simple linear mixed effects model for a longitudinal marker, it gives the basic structure of the function. The required arguments are:

- formLong: formula for the model with the lme4 structure (including random effects in the formula as: (NAME | ID)).
- o dataLong: Dataset that must contains the variables given in the formula.
- $\circ~$ id: Name of the variable for grouping (e.g., individuals).
- timeVar: Name of the time variable.
- family: Distribution of the outcome (e.g., gaussian, poisson, binomial).

The model structure is given by the following equation:

$$\log(serBilir_{ij}) = \beta_0 + b_{i0} + \beta_1 year_{ij} + \beta_2 drug_i + \varepsilon_{ij}$$
 (L1)

where β are the fixed effects, b_{i0} is an individual random intercept and ε_{ij} is the residual error term.

The summary statistics are available from the $\ensuremath{\mathsf{summary}}$ function:

```
## Longitudinal outcome (lognormal)
## Longitudinal outcome (lognormal)
## mean sd 0.025quant 0.5quant 0.975quant
## Intercept_L1 0.6247 0.0879 0.4523 0.6246 0.7970

## Widely applicable Bayesian information criterion: 4806.454
## Computation time: 0.95 seconds
```

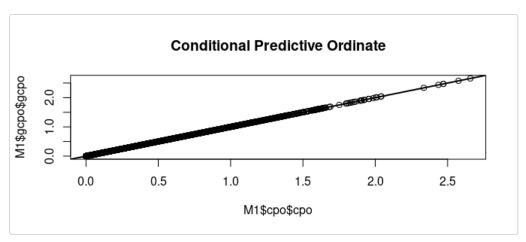

If one wishes to get the standard deviations instead of variance parameters, it is possible to switch with the sdcor argument of the summary function:

```
summary(M1, sdcor=TRUE)
## Longitudinal outcome (lognormal)
##
                  mean
                          sd 0.025quant 0.5quant 0.975quant

                                                                -2795.600
##
## Deviance Information Criterion: 4805.133
## Widely applicable Bayesian information criterion: 4806.454
## Computation time: 0.95 seconds
```

The log marginal-likelihood, the Deviance Information Criterion (DIC) and the Widely Applicable Bayesian Information Criterion (WAIC) are provided in the summary statistics.

The Conditional Predictive Ordinate can be plotted as follows:

```
plot(M1$cpo$cpo, M1$gcpo$gcpo, pch = 1, main="Conditional Predictive Ordinate") abline(a = 0, b = 1, lwd = 2)
```

The control argument in the joint function has the following components:

- int.strategy allows to choose the strategy for the numerical integration used to approximate the marginal
 posterior distributions of the latent field. Available options are "ccd" (default), "grid" or "eb" (empirical
 Bayes). The empirical Bayes uses only the mode of the approximations for the integration, which speed up
 and simplifies computations.
- priorFixed allows to set the mean and standard deviation of the Gaussian prior for the fixed effects.
- priorAssoc allows to set the mean and standard deviation of the Gaussian prior for the association parameters between the longitudinal and survival submodels.

An useful function to learn about the priors used in a fitted model is priors.used, applied to an object fitted with the joint function. The default priors are Gaussian with mean zero and scale 1.

```
priors.used(M1)
```

The full list of the arguments is available in the help documentation of the joint function which can be accessed by running <code>?joint</code>.

Model 2: multiple longitudinal markers with different distributions

The following code fits a joint model with 3 longitudinal markers including fixed effects for covariates such as sex, drug and interactions with time. We assume random intercept and random slope for each longitudinal trajectory. Note that the formLong argument is now a list of formulas, one for each longitudinal marker and the length of family must match the number of markers.

The model structure is given by the following equation:

```
\begin{cases} \log(serBilir_{ij}) &= \beta_{10} + b_{i10} + (\beta_{11} + b_{i11})year_{ij} + \beta_{12}drug_i + \beta_{13}sex_i + \beta_{14}year_{ij}drug_i + \varepsilon_{ij1} & \text{(L1)} \\ \log(E[platelets_{ij}]) &= \beta_{20} + b_{i20} + (\beta_{21} + b_{i21})year_{ij} + \beta_{22}sex_i + \beta_{23}drug_i + \beta_{24}year_{ij}sex_i & \text{(L2)} \\ \log(E[spiders_{ij}]) &= \beta_{30} + b_{i30} + (\beta_{31} + b_{i31})year_{ij} + \beta_{32}drug_i + \beta_{33}year_{ij}drug_i & \text{(L3)} \end{cases}
```

```
M2 <- joint(formLong = list(serBilir ~ year * drug + sex + (1+year|id),
                           platelets ~ year * sex + drug + (1+year|id),
                           spiders ~ year * drug + (1+year| id)),
           dataLong = Longi, id = "id", timeVar="year", corLong=TRUE,
            family = c("lognormal", "poisson", "binomial"), control=list(int.strategy="eb"))

The additional boolean argument <code>corLong</code> is set to TRUE in order to have correlation between the random effects accross the longitudinal markers. Therefore by switching this argument to TRUE, instead of having 3 sets of two correlated random effects, we have 1 set of 6 correlated random effects.

We can also get the standard deviation and correlation of random parameters instead of variance and covariance by adding sdcor=TRUE to the summary function call:

```
summary(M2, sdcor=TRUE)

The link functions between the linear predictors and the longitudinal outcomes are set to default, it is however possible to switch to alternative ones using the link argument, e.g., to switch from logit to probit for the binary marker:

```
M2 <- joint(formLong = list(serBilir ~ year * drug + sex + (1+year|id),
                   platelets ~ year * sex + drug + (1+year|id),
                   spiders \sim (1 + year) * drug + (1+year| id)),
        dataLong = Longi, id = "id", timeVar="year", corLong=TRUE,
        family = c("lognormal", "poisson", "binomial"),
        link = c("default", "default", "probit"), control=list(int.strategy="eb"))

Model 3: longitudinal - survival joint model

Some additional arguments are introduced to fit a joint model with a survival component and to set up the association between the longitudinal and survival parts:

- formSurv: formula for the time-to-event outcome, with the response given as an inla.surv() object.
- dataSurv: Optional, if not provided the longitudinal dataset is used to get the covariates values included in the time-to-event formula.
- basRisk: the baseline risk of event. There are two options: "rw1" for random walks of order one prior that
 corresponds to a smooth spline function based on first order differences. The second option "rw2" assigns
 a random walk order two prior that corresponds to a smooth spline function based on second order
 differences. This second option provides a smoother spline compared to order one since the smoothing is
 then done on the second order. We only propose non-parametric functions for the baseline risk at the
 moment as it is a flexible approach that avoids parametric assumptions.
- assoc: a character string that specifies the association between the longitudinal and survival components.
 The available options are "CV" for sharing the current value of the linear predictor, "CS" for the current slope, "CV_CS" for the current value and the current slope, "SRE" for shared random effects (i.e., sharing the individual deviation from the mean at time t as defined by the random effects), "SRE_ind" for shared random effect independent (each random effect's individual deviation is associated to an association parameter in the survival submodel) and "" (empty string) for no association.

The model structure is given by the following equation:

$$\begin{cases} log(serBilir_{ij}) &= \eta_i(t_{ij}) + \varepsilon_{ij} \\ &= \beta_0 + b_{i0} + (\beta_1 + b_{i1})year_{ij} + (\beta_2 + b_{i2})drug_i \\ &+ (\beta_2 + b_{i2})year_{ij}^2 + (\beta_3 + b_{i3})year_{ij}^3 + \varepsilon_{ij} \end{cases} \\ \lambda_{i1}(t) &= \lambda_{01}(t) \exp\left(\gamma_1 sex_i + \gamma_2 drug_i + \varphi_1 \eta_i(t) + \varphi_2 \eta_i^{'}(t)\right) \quad (S1) \end{cases}$$

where γ denotes fixed effects of the survival part and φ the association parameters.

```

In case some functions of time should be included, they must be set as illustrated in the above example; i.e., create a univariate function of x named f1, f2, ..., fN, and use this function in the formula. This is important to be able to compute the value of the linear predictor at any time t, particularly for the time-dependent association structures. A numerical approximation of the derivative of the function is automatically computed in case the current slope of the linear predictor is shared in the survival submodel.

We can plot the posterior distribution for all the parameters with the plot function

```
plotM3 <- plot(M3, sdcor=T)
```

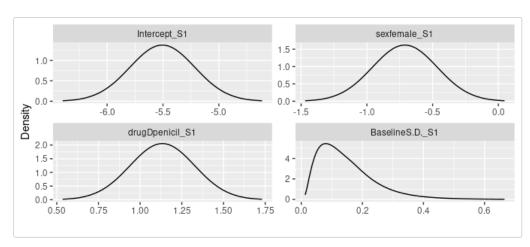

The plot function returns multiple plots for each component of the model. First the plots for the longitudinal outcome(s) parameters:

```
plotM3$Outcomes$L1
```

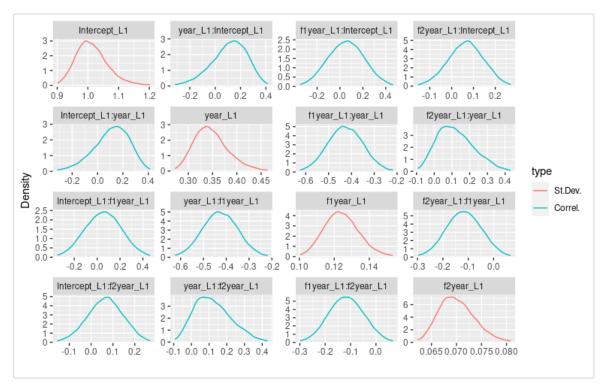

Then the parameters of the survival outcome(s):

plotM3\$Outcomes\$S1

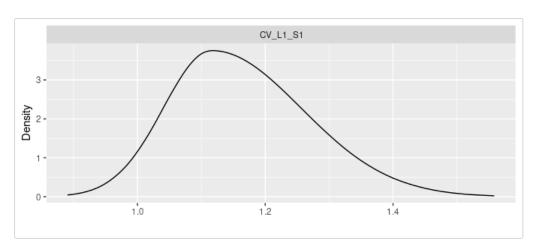

The variance-covariance of the random-effects (converted to standard deviations and correlations when argument sdcor=TRUE is added to the call of the plot function):

plotM3\$Covariances

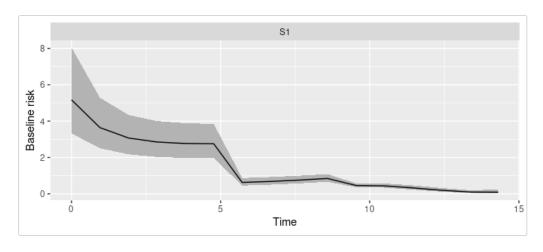

The posterior distributions of the association parameters:

plotM3\$Associations

And finally the curve for the baseline risk functions:

plotM3\$Random

Model 4: Comparison with MCMC

We can make a comparison of INLAjoint with Bayesian estimations with MCMC implemented in alternative R packages such as JMBayes (JAGS) or rstanarm (Stan).

We propose a comparison for a simple joint model with one longitudinal and one survival component:

```
\begin{cases} albumin_{ij} &= \eta_i(t_{ij}) + \varepsilon_{ij} \\ &= \beta_0 + b_{i0} + (\beta_1 + b_{i1}) year_{ij} + \beta_2 drug_i + \beta_3 year_{ij} drug_i + \varepsilon_{ij} \\ \lambda_i(t) &= \lambda_0(t) \exp\left(\gamma_1 sex_i + \gamma_2 drug_i + \varphi \eta_i(t)\right) \end{cases} \tag{L1}
```

Here the prior distributions of the fixed effects and association parameters are changed to have precision 0.16 (i.e., standard deviation 2.5 instead of the default value of 1), in order to match the default prior distributions of rstanarm for the fixed effects and association parameters.

comp. time	8 sec.	109 sec.	596 sec.

A more detailed comparison between INLA and MCEM and MCMC is available at https://arxiv.org/abs/2203.06256 and a comparison between INLA and Levenberg-Marquardt algorithm (Newton-Raphson like that performs MLE) is available at https://arxiv.org/abs/2010.13704

Model 5: joint with one longitudinal and competing risks of event

In order to account for competing risks of event, the <code>formSurv</code> argument is given as a list with one element for each risk submodel. Moreover, the <code>basRisk</code> argument must be a vector with the same number of elements as the number of survival submodels.

The model structure is given by the following equation:

$$\log(serBilir_{ij}) = \eta_{i}(t_{ij}) + \varepsilon_{ij}$$

$$= \beta_{0} + b_{i0} + (\beta_{1} + b_{i1})year_{ij} + \beta_{2}drug_{i} + \beta_{3}sex_{i}$$

$$+ \beta_{4}year_{ij}drug_{i} + \beta_{5}year_{ij}sex_{i} + \varepsilon_{ij}$$

$$\lambda_{i1}^{death}(t) = \lambda_{01}(t) \exp\left(\gamma_{11}sex_{i} + \gamma_{12}drug_{i} + \varphi_{11}(b_{i0} + b_{i1}t)\right)$$

$$\lambda_{i2}^{transpl.}(t) = \lambda_{02}(t) \exp\left(\gamma_{21}edema_no_{i} + \gamma_{22}edema_de_{i} + \gamma_{23}sex_{i} + \gamma_{24}edema_no_{i}sex_{i} + \gamma_{25}edema_de_{i}sex_{i} + \varphi_{21}b_{i0} + \varphi_{22}b_{i1}\right)$$
(S1)

```
# set up competing time-to-event outcome

Model 6: joint with three longitudinal markers and competing risks of event

When multiple longitudinal submodels and survival submodels are included, the arguments formSurv and formLong are both given as lists. The assoc parameter should then be a list with one element for each longitudinal submodel and each element is a vector for the association with each survival submodel.

The model structure is given by the following equation:

```
\log(serBilir_{ii})
                                      = \eta_{i1}(t_{ij}) + \varepsilon_{ij1} = \beta_{10} + b_{i10} + (\beta_{11} + b_{i11})year_{ij} + \beta_{12}drug_i + \beta_{13}sex_i
                                                                                                                                                          (L1)
                                        +\beta_{14}year<sub>ii</sub>drug<sub>i</sub> + \varepsilon_{ii1}
          log(E[platelets_{ii}]) = \eta_{i2}(t_{ii}) = \beta_{20} + b_{i20} + (\beta_{21} + b_{i21})year_{ii} + \beta_{22}sex_i + \beta_{23}drug_i + \beta_{24}year_{ii}sex_i
                                                                                                                                                        (L2)
          logit(E[spiders_{ii}]) = \eta_{i3}(t_{ii}) = \beta_{30} + b_{i30} + (\beta_{31} + b_{i31})year_{ii} + \beta_{32}drug_i + \beta_{33}year_{ii}drug_i
                                                                                                                                                          (L3)
                                       = \lambda_{01}(t) \exp \left( \gamma_{11} drug_i + \varphi_{11} \eta_{i1}(t) + \varphi_{12}(b_{i20} + b_{i21}t) + \varphi_{13} \eta_{i3}(t) + \varphi_{14} \eta_{i3}^{'}(t) \right)
                                                                                                                                                          (S1)
                                       = \lambda_{02}(t) \exp\left(\gamma_{21} drug_i + \varphi_{21} \eta_{i1}(t) + \varphi_{22} \eta_{i3}'(t)\right)
                                                                                                                                                          (S2)

The longitudinal markers are assumed correlated but it is also possible to set corLong to FALSE to have independent random effects across markers and reduce the number of covariance parameters.

Model 7: model from application section of

https://arxiv.org/abs/2203.06256

The model structure is given by the following equation:

$$\begin{array}{ll} \log(serBilir_{ij}) & = \eta_{i1}(t_{ij}) + \varepsilon_{ij1} & (L1) \\ & = (\beta_{10} + b_{i10}) + \beta_{11}X_i + (\beta_{12} + b_{i11})\mathrm{NS}_1(t_{ij}) + (\beta_{13} + b_{i12})\mathrm{NS}_2(t_{ij}) \\ & + (\beta_{14} + b_{i13})\mathrm{NS}_3(t_{ij}) + \beta_{15}X_i\mathrm{NS}_1(t_{ij}) + \beta_{16}X_i\mathrm{NS}_2(t_{ij}) + \beta_{17}X_i\mathrm{NS}_3(t_{ij}) + \varepsilon_{ij1} \\ \log(SGOT_{ij}) & = \eta_{i2}(t_{ij}) + \varepsilon_{ij2} & (L2) \\ & = (\beta_{20} + b_{i20}) + \beta_{21}X_i + (\beta_{22} + b_{i21})\mathrm{NS}_1(t_{ij}) + (\beta_{23} + b_{i22})\mathrm{NS}_2(t_{ij}) \\ & + (\beta_{24} + b_{i23})\mathrm{NS}_3(t_{ij}) + \beta_{25}X_i\mathrm{NS}_1(t_{ij}) + \beta_{26}X_i\mathrm{NS}_2(t_{ij}) + \beta_{27}X_i\mathrm{NS}_3(t_{ij}) + \varepsilon_{ij2} \\ albumin_{ij} & = \eta_{i3}(t_{ij}) + \varepsilon_{ij3} & (L3) \\ & = (\beta_{30} + b_{i30}) + \beta_{31}X_i + (\beta_{32} + b_{i31})t + \beta_{33}X_it + \varepsilon_{ij3} \\ \log(E[platelets_{ij}]) & = \eta_{i4}(t_{ij}) & (L4) \\ & = (\beta_{40} + b_{i40}) + \beta_{41}X_i + (\beta_{42} + b_{i41})\mathrm{NS}_1(t_{ij}) + (\beta_{43} + b_{i42})\mathrm{NS}_2(t_{ij}) \\ & + (\beta_{44} + b_{i43})\mathrm{NS}_3(t_{ij}) + \beta_{45}X_i\mathrm{NS}_1(t_{ij}) + \beta_{46}X_i\mathrm{NS}_2(t_{ij}) + \beta_{47}X_i\mathrm{NS}_3(t_{ij}) \\ \logit(E[spiders_{ij}]) & = \eta_{i5}(t_{ij}) & (L5) \\ & = (\beta_{50} + b_{i50}) + \beta_{51}X_i + (\beta_{52} + b_{i51})t + \beta_{53}X_it \\ \lambda_{i1}(t) & = \lambda_{01}(t) \exp\left(\gamma_1X_i + \varphi_1\eta_{i1}(t) + \varphi_3\eta_{i1}^{'}(t) + \varphi_4\eta_{i2}(t) \\ & + \varphi_5\eta_{i3}(t) + \varphi_7\eta_{i4}(t) + \varphi_9\eta_{i5}(t)\right) \\ \lambda_{i2}(t) & = \lambda_{02}(t) \exp\left(\gamma_2X_i + \varphi_2\eta_{i1}(t) + \varphi_6\eta_{i3}(t) + \varphi_8\eta_{i4}(t)\right) & (S2) \end{array}$$

where $NS_1(t)$, $NS_2(t)$, $NS_3(t)$ are the natural cubic splines with internal knots at 1 and 4 years. We assume independent random effects between longitudinal markers.
